## Introduction

In wine, aroma perception is shaped by complex interactions between volatile and non-volatile components. Among the latter, oenological tannins (OETs) are commonly added during winemaking for their antioxidant and stabilizing properties, making them an interesting alternative to traditional chemical preservatives such as SO<sub>2</sub>. Furthermore, OETs can modulate the volatility of aroma compounds. Therefore, this study investigates whether the pre-fermentative addition of OETs can influence the color characteristics and volatile organic compounds (VOCs) of white wines, thereby enhancing aroma complexity.

## Conclusion

With respect to the volatile composition, Favorita was more responsive to tannin addition. QB increased total VOCs at the end of fermentation (P3), particularly esters, higher alcohols and volatile acids compared to control, and helped to better preserve norisoprenoids (Figure 1 and 3). In Erbaluce, the effects of OETs addition were less pronounced and significant differences were not found for total VOCs (Figure 2 and 4). These findings demonstrate that aroma modulation is both tannin and grape variety dependent.

The pre-fermentative addition of oenological tannins modulated the volatile profile of white wines, particularly in Favorita variety. The effect was influenced by both the tannin type and the grape variety. Certain tannin formulations, such as QB, showed promising potential for enhancing aromatic complexity without significantly affecting wine colour. These findings suggest that the aroma modulation is not only influenced by antioxidant capacity and further support the use of oenological tannins as a valuable enological tool.
